1

Task 1

1. What is the purpose of HTTP cookies?
2. Consider the following scenario. A client requests the same resource on the server for several times. Each time he requests a resource, the number of prior requests is returned in the resource representation. Complete the following diagram with missing HTTP headers and status codes required for implementation of the above

Client

Server
(example.org)

GET /index.html

HTTP/1.1

This is your 1. visit

GET /index.html

HTTP/1.1

This is your 2. visit

GET /index.html

HTTP/1.1

This is your 3. visit

TECHNISCHE UNIVERSITÄT
CHEMNITZ

Client

Server
(example.org)

GET /index.html HTTP/1.1

Host: example.org

Cookie: counter=1;

HTTP/1.1 200 OK

Set-Cookie: counter=2

This is your 2. visit

Client

Server
(example.org)

GET /index.html HTTP/1.1

Host: example.org

Cookie: counter=2;

HTTP/1.1 200 OK

Set-Cookie: counter=3

This is your 3. visit

1. What is the purpose of HTTP cookies?
2. Consider the following scenario. A client requests the same resource on the server for several times. Each time he requests a resource, the number of prior requests is returned in the resource representation. Complete the following diagram with missing HTTP headers and status codes required for implementation of the above scenario
3. Extend the template *Task1-Template.zip* towards the above scenario.

2 Task 2

1. Answer the following questions.
   a) What is SOAP?
   b) Where would you situate SOAP within the Internet Protocol stack?
   c) Which parts are in a SOAP Message?

- SOAP is a protocol for the exchange of information in a distributed environment. SOAP messages are encoded as XML documents and can be exchanged using a variety of underlying protocols

Application	SOAP				
	HTTP	HTTPS	SMTP	Etc.	Over TCP

- A SOAP message is encoded as an XML document, consisting of an <Envelope> element, which contains an optional <Header> element, and a mandatory <Body> element. The <Fault> element, contained within the <Body>, is used for reporting errors.

TECHNISCHE UNIVERSITÄT CHEMNITZ

1. Answer the following questions.
   a) What is SOAP?
   b) Where would you situate SOAP within the Internet Protocol stack?
   c) Which parts are in a SOAP Message?
2. Under http://vsr-demo.informatik.tu-chemnitz.de/webservices/SoapWebService/Service.asmx you will find a simple Web service, which is able to compute a sum of two integers (the Add operation). Implement a client for sending SOAP1.2 requests to the above service based on the template *Task2-Template.zip*. Print the result of the calculation to the console.

3 Homework

a) Complete the *GenericSOAPClient.Invoke* method of the Assignment1-Template.zip project, which should be able to send requests to ANY SOAP service using given service URL, service namespace, operationName and named parameters list (for simplicity request and response parameters can be only strings or integers). Test your class on the service above and the ConcatenatorService under

http://vsr-demo.informatik.tu-chemnitz.de/webservices/ConcatenatorService/ConcatenatorService.asmx

b) The project *Assignment2-Template.zip* contains a distributed system including a server, a broker and two clients. The Server sends regular stock price updates to the broker, which distributes them to the both clients. The broker is often overloaded and therefore the server should retransmit the message if broker doesn't acknowledge the message receipt (**robust one-way** MEP). The communication between the broker and clients should follow simple **one-way** MEP.
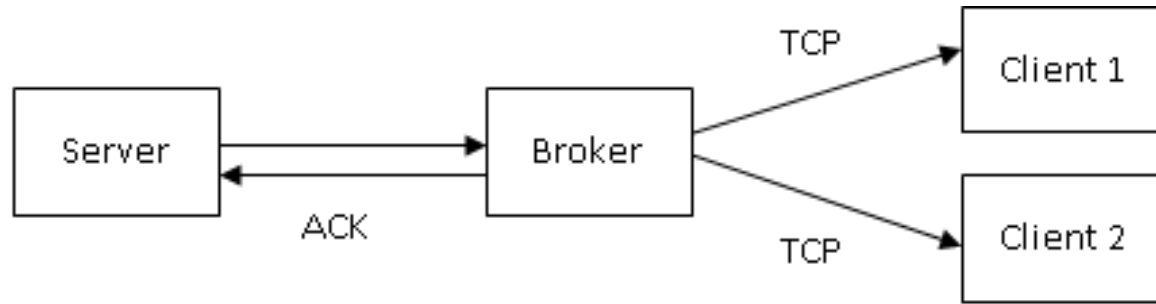

- Extend the *ReceiveMessage* method of the broker to send SOAP-based receipt notifications back to the server (BUSY or RECIEVED).
- The broker should not be able to read the contents of some SOAP messages. Update the server and **client 1** to use shared secret to encrypt and decrypt contents of SOAP messages.
- **Client 2** should not be equipped with any encryption/decryption facilities and therefore ignore encrypted messages. Make server send appropriate SOAP headers to signal the need of decrypting content before processing it.
